Introduction

The Citrix Provisioning Server enables organizations to reduce the number of systems that they manage, even as the number of computers continues to grow. This solution simultaneously provides the efficiencies of a centrally managed solution with the benefits of distributed processing.

This solution's infrastructure is based on software-streaming technology. Using Provisioning Server, administrators prepare a device (Master Target Device) for imaging by installing any required software on that device. A vDisk image is then created from the Master Target Device's hard drive and saved to the network (on a Provisioning Server or storage device). Once the vDisk is available from the network, the target device no longer needs its local hard drive to operate; it boots directly across the network. The Provisioning Server streams the contents of the vDisk to the target device on demand, in real time. The target device behaves as if it is running from its local drive.

Snags in the normal functioning of the Provisioning server – for instance, the inability of the server to connect to the database/License server, or, the existence of corrupt image files on the server - can not only delay virtual desktop provisioning in XenDesktop environments, but can also cause inexplicable errors in the streaming of vDisk contents to target devices.

To ensure that such anomalies do not scar the user experience with the Provisioning server, 24 x 7 monitoring of the server is essential. Besides promptly capturing current performance issues, periodic monitoring can also provide early warning signals of probable issues. eG Enterprise offers a 100%, web-based *Citrix Provisioning Server* monitoring model that periodically monitors the Citrix provisioning servers in a farm to promptly alert administrators before anything untoward happens.

Monitoring Citrix provisioning Server

eG Enterprise offers a 100%, web-based *Citrix Provisioning Server* monitoring model that periodically monitors the Citrix provisioning servers in a farm, and promptly updates the administrator with the status of the Provisioning servers, the target devices they manage, the vDisks they create, and the licensing and database servers they communicate with.

Figure 2.1: The layer model of the Citrix Provisioning server

Each layer of Figure 1 above is mapped to a variety of tests that shed light on the health of the operating system, network, and critical services offered by the Provisioning server. Each test executes a command supported by the **Management Command Line Interface (MCLI)** of the Citrix Provisioning server to collect the required metrics. To enable the tests to use MCLI, the eG agent should fulfill the certain pre-requisites that are detailed in Section 2.1 .

Using the metrics reported by the tests, the following performance queries can be accurately answered:

- Is the License server in the Provisioning Services farm available?
- Is the Provisioning server able to connect to its database?
- How many sites, servers, stores, and farm views does the Provisioning server farm comprise of?
- Are there any inactive servers and inactive devices in the site?

- Which are the inactive vDisks in the vDisk pool?
- Which vDisks in the vDisk pool are not connected to any target devices?
- Are any vDisks locked? Are any target devices mapped to such vDisks?
- Is the write-cache of any vDisk growing at an alarming rate?
- Have any errors been recently captured by the error log?
- Which device collection consists of the maximum number of inactive devices? Which devices in the collection are inactive?

The sections that follow will discuss each layer of Figure 2.1 in great detail.

2.1 Pre- requisites for monitoring the Citrix Provisioning Server

The tests execute a command supported by the **Management Command Line Interface (MCLI)** of the Citrix Provisioning server to collect the required metrics. To enable the tests to use MCLI, the eG agent should fulfill the following pre-requisites:

1. The eG agent should be deployed on the Citrix Provisioning server;

Note:

The Citrix Provisioning server cannot be monitored in an *agentless* manner.

2. The eG agent should run using the permissions of a user who fulfills the following requirements:

- Should belong to the *Security* group with 'Farm Administrator' access.
- Should be assigned the **Allow log on locally** security privilege on the Citrix PVS host.

The steps for assigning such a user are as follows:

- To add the security group to Citrix PVS and grant 'Farm Administrator' rights to it. The steps in this regard are as follows:
 - Login to the Citrix PVS host and open the Citrix Provisioning Services console. Figure 2.2 will then appear.

Figure 2.2: The Citrix PVS Console

- Right-click on the node representing the PVS farm in the tree structure in the left panel of the console, and pick the **Properties** option from the shortcut menu that pops up (see Figure 2.3).

Figure 2.3: Selecting the Properties option

- Once the **Farm Properties** dialog box appears, click the **Groups** tab page within to view the security groups in PVS. By default, only the *Administrators* group will be available therein, and it will be selected by default indicating that only users in the *Administrators* group are allowed full access to the PVS farm. To add a new group, click the **Add** button in Figure 2.4.

Figure 2.4: Viewing the Security Group that is allowed access to the PVS farm by default

- Figure 2.5 then appears. To search for the security group to be added to PVS, click the **Search** button in Figure 5. Doing so will display all available domains/groups. From this list, select the security group that contains the user using whose credentials the eG agent needs to run. For selection, click on the check box that pre-fixes the security group, and click the **OK** button in Figure 2.5.

Figure 2.5: Adding a new Security Group to PVS

- This will lead you to Figure 2.6, where the newly added group will be displayed. Select the new addition to grant access rights to it.

Figure 2.6: Selecting the new group to set it as the Security Group that is allowed access to the PVS farm

- Then, click the **Security** tab page. Here again, the newly added group will be displayed. To grant 'Farm Administrator' access to it, select the new security group and click the **OK** button.

Figure 2.7: Granting 'Farm Administrator' access to the newly added Security group

- Next, the user who is the part of the security group should also be assigned the **Allow log on locally** security privilege on the Citrix Provisioning host. To assign this privilege, do the following:
 - Go to the **Control Panel** in the host.
 - From the list of control panel items, click the **Administrative Tools** to view the set of tools available for system administrators and advanced users.
 - Upon selecting the **Local Security Policy** tool in the **Administrative Tools** location, the **Local Security Policy** settings console will appear.
 - Next, navigate to the **User Rights Assignment** node in the **Local Policies** tree in the left panel of the settings console. This will display the security policies corresponding to the user rights in

the right panel.

- Now, select the **Allow log on locally** policy to assign the security privilege to the user.
- Once this is done, you can proceed to configure every test that the eG agent executes on Citrix PVS with the **DOMAIN NAME**, **DOMAIN USER**, and **DOMAIN PASSWORD** of the domain user who is part of the *Security Group* and assigned with the *Allow log on locally* security privilege.

2.2 The Operating System Layer

Use the tests mapped to this layer to understand the current health of the operating system that runs the Citrix Provisioning server.

Figure 2.8: The tests mapped to the Operating System layer

Since the tests depicted by Figure 2.8 have already been dealt with in the *Monitoring Generic Servers* document, let us proceed to the next layer.

2.3 The Network Layer

Sudden breaks in the network availability of the server and unusual increase in network traffic to / from the server will be captured and reported by the tests mapped to this layer.

Figure 2.9: The tests mapped to the Network layer

Since the tests depicted by Figure 2.9 have already been dealt with in the *Monitoring Generic Servers* document, let us proceed to the next layer.

2.4 The Tcp Layer

This layer monitors the health of TCP connections to and from the Citrix Provisioning server.

Figure 2.10: The test mapped to the Tcp layer

Since the test depicted by Figure 2.10 have already been dealt with in the *Monitoring Generic Servers* document, let us proceed to the next layer.

2.5 The Application Processes Layer

The status and resource usage of processes critical to the operations of the Citrix Provisioning server are monitored by this layer.

Application Processes	
Processes	Process Status
✓ BNPXE	
✓ BNTFTP	
✓ PVSTSB	
✓ soapserver	
✓ StreamProcess	
✓ StreamService	
TCP Port Status	Port Status
✓ 54321	
✓ 54322	
Windows Processes	Process Status
✓ BNPXE	
✓ BNTFTP	
✓ PVSTSB	
✓ soapserver	
✓ StreamProcess	
✓ StreamService	

Figure 2.11: The tests mapped to the Application Processes layer

Since the tests depicted by Figure 2.11 have already been dealt with in the *Monitoring Generic Servers* document, let us proceed to the next layer.

2.6 The Windows Service Layer

This layer reports the availability of critical services on the Windows host that runs the Citrix Provisioning server, and also monitors the system/application/security logs for error or warning events that may have been captured recently.

Figure 2.12: The tests mapped to the Windows Service layer

2.7 The PVS Platform Layer

Using the tests mapped to this layer, you can determine the following:

- The contents of a Citrix Provisioning services farm
- The active/inactive state of servers, target devices, and vDisks in a site
- The size and state of vDisks in a vDisk pool
- The number and nature of errors logged in the error log

Figure 2.13: The tests mapped to the PVS Platform layer

2.7.1 PVS Farm Test

A farm represents the top level of a Provisioning Server infrastructure. Farms provide a “*Farm Administrator*” with a method of representing, defining, and managing logical groups of Provisioning Server components into sites.

All sites within a farm share that farm’s Provisioning Server MS SQL database. A farm also includes a Citrix License Server, local or network shared storage, and collections of target devices.

Using this test, you can understand the composition of your Citrix Provisioning server farm, and can also be proactively alerted to critical problems such as:

- A sudden break in the connectivity between the Provisioning server farm and the Citrix Licensing server;
- Inaccessibility of the database server

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : One set of results for every Citrix Provisional server farm being monitored

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is 54321.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface (MCLI)** of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:
 - Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: *<System_Root>\Program Files\Citrix\Provisioning Services Console*
 - In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: *<System_Root>\Program Files (x86)\Citrix\Provisioning Services Console*
5. **DOMAIN NAME, DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:
 - Should belong to the Security group with ‘Farm Administrator’ access.
 - Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning Server host.

The steps for assigning such privileges to a user are detailed in the Section **2.1**.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN**

NAME, DOMAIN USER, and DOMAIN PASSWORD of the same user.

6. **DETAILED DIAGNOSIS** - To make diagnosis more efficient and accurate, the eG Enterprise suite embeds an optional detailed diagnostic capability. With this capability, the eG agents can be configured to run detailed, more elaborate tests as and when specific problems are detected. To enable the detailed diagnosis capability of this test for a particular server, choose the **On** option. To disable the capability, click on the **Off** option.

The option to selectively enable/disable the detailed diagnosis capability will be available only if the following conditions are fulfilled:

- The eG manager license should allow the detailed diagnosis capability;
- Both the normal and abnormal frequencies configured for the detailed diagnosis measures should not be 0.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
License server availability:	Indicates the availability of the Citrix License Server which is used to hold the Citrix Provisioning Server licenses.	Percent	<p>If the value returned is 0, it indicates that the farm is not able to reach the Citrix License server. The value 100 indicates that the License server is accessible.</p> <p>If a Citrix License server is suddenly rendered unavailable, then all active Provisioning Services clients will continue working until a restart occurs. If the License server continues to remain unavailable during startup, then the clients go to grace period; till the end of the grace period of 720 hours, the Provisioning Services clients continue working. Once the grace period ends, the clients restart again. If the Citrix License server is still unavailable, then the clients receive a five-minute shutdown-warning message; at the end of the 5 minutes, the clients shutdown.</p> <p>If the License server is unavailable, you may want to use the detailed diagnosis of this measure to determine the IP address and port number of the License server, so that further investigations can</p>

Measurement	Description	Measurement Unit	Interpretation
			be performed.
Database server availability:	Indicates the availability of the Provisioning server database.	Percent	<p>If the value returned is 0, it is indicative of the absence of connectivity between the farm and its database. The value 100 on the other hand indicates that the database is accessible.</p> <p>A PVS Farm uses a Microsoft SQL database to store all Farm information. Provisioning Services supports a variety of Microsoft SQL database platforms (MS SQL 2005, MS SQL 2008, MS SQL 2008R2, and Express as of this writing). The availability of the database is critical to the operation of the PVS Farm. If the database is not available then no Target Devices will be able to boot and receive a streamed vDisk.</p> <p>In the event of the non-availability of the database therefore, you may want to use the detailed diagnosis of this measure to determine the IP address and port number of the database server, so that further investigations can be performed.</p>
Sites count:	Indicates the number of sites that have been configured in this farm.	Number	<p>A site provides both a “Site Administrator” and farm administrator, with a method of representing and managing logical groupings of Provisioning Servers, Device Collections, and local shared storage.</p> <p>To know which sites are part of the farm, use the detailed diagnosis of this measure.</p>
Servers count:	Indicates the number of Citrix Provisioning servers	Number	To know which servers are part of the farm, use the detailed diagnosis of this measure.

Measurement	Description	Measurement Unit	Interpretation
	as member servers in the Citrix Provisioning server farm.		
Stores count:	Indicates the number of stores created in the Citrix Provisioning server farm.	Number	<p>A store is a logical name that is given to a physical vDisk storage location. The store name is the common name used by all Provisioning Servers within the farm.</p> <p>To know which stores are part of the farm, use the detailed diagnosis of this measure.</p>
Farm views defined:	Indicates the number of views created in the Citrix Provisioning server.	Number	<p>You can create views containing target devices to display only those target devices that you are currently interested in viewing or performing tasks on. Adding target devices to a view provides a quick and easy way to perform a task on members of that view, such as:</p> <ul style="list-style-type: none"> • Boot • Restart • Shutdown • Send message <p>Views can be created at the site level or at the farm level.</p> <p>To know which views are part of the farm, use the detailed diagnosis of this measure.</p>

The detailed diagnosis of the *License server availability* measure allows you to view the IP address and port number of the License server used by a farm. If the License server is unavailable, you may want to use the detailed diagnosis of this measure to determine the IP address and port number of the License server, so that further investigations can be performed.

2.7.2 PVS Servers Test

This test auto-discovers the Provisioning servers in the Provisioning server farm that is being monitored, and reports the following for each server in that farm.

- The server status
- Whether target devices are connected to the server or not
- Whether/not the server has been configured with the right amount of ports and threads per port to handle streaming requests from targets

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : By default, the test reports one set of results for each server in the Citrix Provisional server farm being monitored

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is 54321.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface (MCLI)** of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:

- Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: <System_Root>|Program Files|Citrix|Provisioning Services Console
- In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: <System_Root>|Program Files (x86)|Citrix|Provisioning Services Console

5. **DOMAIN NAME, DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:

- Should belong to the Security group with 'Farm Administrator' access.
- Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning Server host.

The steps for assigning such privileges to a user are detailed in the Section **2.1**.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN NAME, DOMAIN USER**, and **DOMAIN PASSWORD** of the same user.

6. **LOCAL HOST ONLY** - By default, this flag is set to **No**. This implies that, by default, the test auto-discovers all the servers that are part of the PVS farm, and reports metrics for each server. Setting the flag to **Yes** ensures that the test reports metrics for only that server, which is being monitored.

7. **DETAILED DIAGNOSIS** - To make diagnosis more efficient and accurate, the eG Enterprise suite embeds an optional detailed diagnostic capability. With this capability, the eG agents can be configured to run detailed, more elaborate tests as and when specific problems are detected. To enable the detailed diagnosis capability of this test for a particular server, choose the **On** option. To disable the capability, click on the **Off** option.

The option to selectively enable/disable the detailed diagnosis capability will be available only if the following conditions are fulfilled:

- The eG manager license should allow the detailed diagnosis capability;
- Both the normal and abnormal frequencies configured for the detailed diagnosis measures should not be 0.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
Server status:	Indicates the current status of this server.		<p>This measure reports the value Active if the Provisioning server is currently available for providing Provisioning services. If the server is not available, then this measure will report the value Inactive.</p> <p>The numeric values that correspond to the states mentioned above are as</p>

Measurement	Description	Measurement Unit	Interpretation								
			<p>follows:</p> <table border="1" data-bbox="1003 382 1379 580"> <thead> <tr> <th data-bbox="1003 382 1199 454">Numeric Value</th><th data-bbox="1199 382 1379 454">Measure Value</th></tr> </thead> <tbody> <tr> <td data-bbox="1003 454 1199 496">0</td><td data-bbox="1199 454 1379 496">Otherwise</td></tr> <tr> <td data-bbox="1003 496 1199 538">1</td><td data-bbox="1199 496 1379 538">Active</td></tr> <tr> <td data-bbox="1003 538 1199 580">2</td><td data-bbox="1199 538 1379 580">Unknown</td></tr> </tbody> </table> <p>Note:</p> <p>By default, this measure reports the values Measure Values listed in the table above to indicate the status of a Provisioning server. The graph of this measure however, represents the status of a server using the numeric equivalents only - 0 - 2.</p>	Numeric Value	Measure Value	0	Otherwise	1	Active	2	Unknown
Numeric Value	Measure Value										
0	Otherwise										
1	Active										
2	Unknown										
Total target devices:	Indicates the number of target devices that are currently connected to this server.	Number	Use the detailed diagnosis of this measure to know which target devices are connected to the server. The device information provided by the detailed diagnosis include the name of the target device, the vDisk associated with the device, the IP address of the server to which the device is connected, the port at which the server listens, and the number of retries.								
Threads per port Vs Logical processors:	Indicates whether this server is configured in optimal or sub-optimal manner.	Number	On a PVS server, the Threads Per Port configuration governs the quality of communication between the Stream service and target devices. This setting indicates the number of threads in the thread pool that service UDP packets received on a given UDP port. Larger number of threads allow more target device requests to be processed simultaneously, but it consumes more system resources. If there are more threads, but less system resources,								

Measurement	Description	Measurement Unit	Interpretation						
			<p>request processing is bound to suffer, as the excess threads will simply block waiting for I/O. This is why, the optimal configuration is to have more cores and less threads - i.e., the number of threads per port should be lesser than the number of cores. A sub-optimal configuration would be to have less cores and more threads per port.</p> <p>To quickly indicate to administrators whether a threads per port configuration is optimal / not, this measure reports the following values:</p> <ul style="list-style-type: none"> • <i>Optimal Configuration</i>, if the number of cores is greater than the number of threads per port. • <i>Sub-optimal Configuration</i>, if the cores on the server is lesser than the threads per port. <p>The numeric values that correspond to these measure values are as follows:</p> <table border="1" data-bbox="1002 1205 1383 1438"> <thead> <tr> <th data-bbox="1002 1205 1188 1269">Measure value</th><th data-bbox="1188 1205 1383 1269">Numeric Value</th></tr> </thead> <tbody> <tr> <td data-bbox="1002 1269 1188 1347">Optimal Configuration</td><td data-bbox="1188 1269 1383 1347">1</td></tr> <tr> <td data-bbox="1002 1347 1188 1438">Sub-optimal Configuration</td><td data-bbox="1188 1347 1383 1438">2</td></tr> </tbody> </table> <p>By bringing a sub-optimal configuration to the immediate attention of administrators, this measure prompts them to quickly fine-tune the Threads Per Port setting, so that potential processing bottlenecks can be eliminated.</p> <p>Note:</p> <p>By default, this measure reports the</p>	Measure value	Numeric Value	Optimal Configuration	1	Sub-optimal Configuration	2
Measure value	Numeric Value								
Optimal Configuration	1								
Sub-optimal Configuration	2								

Measurement	Description	Measurement Unit	Interpretation
			<p>Measure Values listed in the table above to indicate the threads per port configuration of a Provisioning server. The graph of this measure however, represents the same using the numeric equivalents only.</p>
Active target device connections:	Indicates the number of streaming requests from target devices currently serviced by this server.	Number	This measure serves as a good indicator of the current workload of the Citrix PVS server.
Threads per port:	Indicates the number of threads in the thread pool that this server should use to service UDP packets received on a given UDP port.	Number	<p>The value of these two measures are in fact server configurations, which if not set correctly, can adversely impact the performance of the PVS server.</p> <p>The <i>Ports</i> measure for instance denotes the number of ports in the Port Range set for the server. The Port Range is nothing but a range of ports used by the Stream Service for target device communications. By default, 20 ports are configured for target device communications.</p> <p>You can also configure the number of threads that each of the configured ports can use to service requests. This is configured using the Threads per port server setting and the same is reported by the Threads per port measure. Larger numbers of threads allow more target device requests to be processed simultaneously, but it consumes more system resources.</p> <p>Together, the two settings discussed above help compute the number of concurrent requests that the PVS server can service. By default, this will be 160 concurrent requests (20 ports * 8 threads</p>

Measurement	Description	Measurement Unit	Interpretation
			<p>per port = 160 requests).</p> <p>In an optimal scenario, you should configure a ports / threads combination that equals the amount of active target devices. So in short, for best performance,</p>
Ports:	Indicates the difference between last port and first port in the port range configured for the Provisioning server.	Number	$\text{"\# of ports"} \times \text{"\# of threads/port"} = \text{"max clients"}$ <p>Also, make sure that your Threads per port setting is not greater than the number of cores available on the PVS server.</p>
Maximum target device connections:	Indicates the maximum number of target device connections this server can handle.	Number	<p>This measure indicates the maximum number of concurrent requests that the PVS server can handle.</p> <p>This is expressed as a product of the value of the Ports measure and that of the Threads per port measure. For instance, if the Ports measure reports the value 20, and Threads per port is 8, then this measure will report the value 160.</p>
Percentage of active device connections:	Indicates what percentage of the Maximum target device connections setting is currently utilized by this server.	Percent	<p>A value close to 100% indicates that the server is currently operating at peak capacity. If the value of this measure crosses 100%, you may end up in a situation where the streaming service cannot process incoming requests right away, as all ports and threads are used by other targets.</p> <p>In this case the rejected target will continue to work without any issue, but you will see a higher read latency for that target as the target has to resend the request and the performance will suffer.</p> <p>In an optimal scenario, you should configure a ports / threads combination</p>

Measurement	Description	Measurement Unit	Interpretation
			<p>that equals the amount of active target devices. So in short, for best performance,</p> <p><i>“# of ports” x “# of threads/port” = “max clients”.</i></p> <p>Also, make sure that your Threads per port setting is not greater than the number of cores available on the PVS server.</p>
Remaining target devices connections:	Indicates how many more requests this server can handle.	Number	<p>The value of this measure is calculated using the following formula:</p> <p><i>Maximum target device connections – [(Connections * Maximum target device connections)/100]</i></p> <p>For example, if the <i>Maximum target device connections</i> measure reports the value 160 and the <i>Target device connections</i> measure reports the value 20%, then the value of this measure will be:</p> $160 - (20/100 * 160) = 128$ <p>Ideally, the value of this measure should be high. A low value or a negative value for this measure implies that all/most of the threads and ports of the server are already in use. Subsequent streaming requests will hence not be serviced right away by the port. This will increase the read latency of the target and cause performance to suffer. You may hence want to allocate more threads and ports to the server using the Port range and Threads per port server properties.</p>

2.7.3 PVS Sites Test

A site provides both a “Site Administrator” and farm administrator, with a method of representing and managing logical groupings of Provisioning Servers, Device Collections, and local shared storage.

Provisioning Servers within a site, communicate with farm components to obtain the information necessary to boot target devices and to provide target devices with the appropriate vDisk.

This test auto-discovers the sites configured within a Provisioning server farm, and reports the number and status of servers, target devices, and vDisks managed by the site.

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : By default, the test reports one set of results for every site configured in the Citrix Provisional server farm being monitored

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is 54321.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface (MCLI)** of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:
 - Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: *<System_Root>|Program Files|Citrix|Provisioning Services Console*
 - In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: *<System_Root>|Program Files (x86)|Citrix|Provisioning Services Console*
5. **DOMAIN NAME**, **DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:
 - Should belong to the Security group with 'Farm Administrator' access.
 - Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning Server host.

The steps for assigning such privileges to a user are detailed in the Section **2.1**.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN NAME**, **DOMAIN USER**, and **DOMAIN PASSWORD** of the same user.
6. **LOCAL HOST ONLY** - By default, this flag is set to **No**. This implies that, by default, the test auto-

discovers all the servers that are part of the PVS farm, and reports metrics for each server. Setting the flag to **Yes** ensures that the test reports metrics for only that server, which is being monitored.

7. **ENABLED DEVICE DD** – By default, this flag is set to **No**. This means that, by default, this test will not report detailed diagnostics for the **Enabled devices** measure – i.e., you will not be able to view the list of enabled devices. To enable the ability of the test to collect and report the list of enabled devices, set this flag to **Yes**.
8. **DISABLED DEVICE DD** - By default, this flag is set to **No**. This means that, by default, this test will not report detailed diagnostics for the **Disabled devices** measure – i.e., you will not be able to view the list of disabled devices. To enable the ability of the test to collect and report the list of disable devices, set this flag to **Yes**.
9. **DETAILED DIAGNOSIS** - To make diagnosis more efficient and accurate, the eG Enterprise suite embeds an optional detailed diagnostic capability. With this capability, the eG agents can be configured to run detailed, more elaborate tests as and when specific problems are detected. To enable the detailed diagnosis capability of this test for a particular server, choose the **On** option. To disable the capability, click on the **Off** option.

The option to selectively enable/disable the detailed diagnosis capability will be available only if the following conditions are fulfilled:

- The eG manager license should allow the detailed diagnosis capability;
- Both the normal and abnormal frequencies configured for the detailed diagnosis measures should not be 0.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
Total servers:	Indicates the total number of Provisioning servers managed by this site.	Number	
Active servers:	Indicates the number of Provisioning servers that are currently active in this site.	Number	Use the detailed diagnosis of this measure to know which servers in the site are active.
Inactive servers:	Indicates the number of inactive servers in this site.	Number	Use the detailed diagnosis of this measure to know which servers in the site are inactive.
Total devices:	Indicates the total number of target devices managed	Number	A target device is a device, such as a desktop computer or server, in a

2.7.4 PVS vDisk Pool Test

A vDisk is an image file stored on a Provisioning Server or remote storage location, which acts as a hard disk for a target device.

vDisk pools are the **collection of all vDisks** available to a site. There is only one vDisk pool per site.

For each vDisk in the vDisk pool, this test reports the size, status, and locked duration.

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : By default, the test reports one set of results for every vDisk in each vDisk pool in the PVS farm being monitored

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is **54321**.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface (MCLI)** of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:
 - Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: *<System_Root>|Program Files|Citrix|Provisioning Services Console*
 - In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: *<System_Root>|Program Files (x86)|Citrix|Provisioning Services Console*
5. **DOMAIN NAME**, **DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:
 - Should belong to the Security group with 'Farm Administrator' access.
 - Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning

Server host.

The steps for assigning such privileges to a user are detailed in the Section **2.1**.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN NAME**, **DOMAIN USER**, and **DOMAIN PASSWORD** of the same user.

6. **LOCAL HOST ONLY** - By default, this flag is set to **No**. This implies that, by default, the test auto-discovers all the servers that are part of the PVS farm, and reports metrics for each server. Setting the flag to **Yes** ensures that the test reports metrics for only that server, which is being monitored.
7. **DETAILED DIAGNOSIS** - To make diagnosis more efficient and accurate, the eG Enterprise suite embeds an optional detailed diagnostic capability. With this capability, the eG agents can be configured to run detailed, more elaborate tests as and when specific problems are detected. To enable the detailed diagnosis capability of this test for a particular server, choose the **On** option. To disable the capability, click on the **Off** option.

The option to selectively enable/disable the detailed diagnosis capability will be available only if the following conditions are fulfilled:

- The eG manager license should allow the detailed diagnosis capability;
- Both the normal and abnormal frequencies configured for the detailed diagnosis measures should not be 0.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
Disk state:	Indicates the current state of this vDisk.		If the value of this measure is Active, it indicates that the vDisk is active and can be used by the target devices connected to it. If the value of this measure is Inactive, it implies that the vDisk is not active and hence, cannot be used by the target devices.
vDisk size:	Indicates the size of this vDisk.	GB	Depending upon the file system used to store the vDisk, the maximum size of a vDisk is 2 terabytes (NTFS) or 4096MB (FAT).
Target device connections:	Indicates the number of target devices that are currently connected to this vDisk.	Number	To know the names of the devices that are currently connected to a vDisk, their IP address, the site in which they operate, and the store they use, take the

Measurement	Description	Measurement Unit	Interpretation						
			help of the detailed diagnosis of this measure.						
Lock status:	Indicates whether this vDisk is currently locked or unlocked.		<p>Since multiple target devices and Provisioning Servers can gain access to a single vDisk image file, it is necessary to control access to prevent corruption of the image. Should a user accidentally assign a private image to multiple target devices, and then try to boot those target devices, a corrupt image would result. Therefore, the image becomes locked appropriately for a given configuration.</p> <p>If a vDisk is locked, then the value of this measure will be Locked. If the lock on a vDisk has been released, then, the value of this measure will be Unlocked.</p> <p>The numeric values that correspond to the states mentioned above are as follows:</p> <table border="1" data-bbox="1008 1146 1383 1305"> <thead> <tr> <th data-bbox="1016 1157 1171 1220">State</th><th data-bbox="1171 1157 1375 1220">Numeric Value</th></tr> </thead> <tbody> <tr> <td data-bbox="1016 1220 1171 1262">Locked</td><td data-bbox="1171 1220 1375 1262">1</td></tr> <tr> <td data-bbox="1016 1262 1171 1305">Unlocked</td><td data-bbox="1171 1262 1375 1305">0</td></tr> </tbody> </table> <p>Note:</p> <p>By default, this measure reports the values <i>Locked</i> or <i>Unlocked</i> to indicate the lock status of a vDisk. The graph of this measure however, represents the lock status using the numeric equivalents - 0 or 1.</p> <p>Be aware that under certain circumstances these locks may not be released properly. A lock on a vDisk image may not be released properly when a target device machine is booted from a vDisk, and then fails (or power is</p>	State	Numeric Value	Locked	1	Unlocked	0
State	Numeric Value								
Locked	1								
Unlocked	0								

Measurement	Description	Measurement Unit	Interpretation
			lost). If the same target device boots again, the same lock is used and no problem occurs. However, if an administrator tries to mount the drive on the Provisioning Server after the target device has failed, the Provisioning Server will not be able to mount that vDisk because a lock is still held by the failed target device. The Administrator has the capability to release these locks.
Locked duration:	Indicates how long this vDisk has been locked.	Mins	If the value of the <i>Lock status</i> measure is Locked for a vDisk, then you can use this measure to determine the duration for which that vDisk was locked. As long as a vDisk remains locked, target devices for which that vDisk has been assigned will not even be able to boot. Hence, a very low value is desired for this measure.

2.7.5 PVS Log Test

This test monitors the Citrix Provisioning server's error logs for errors/warnings of configured patterns, and reports the number of such errors/warnings that have been logged in the log file.

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : One set of results for every alertfile and searchpattern combination

Configurable parameters for the test

1. **TEST PERIOD** - How often should the test be executed
2. **HOST** - The host for which the test is to be configured.
3. **PORT** – The port at which the server listens
4. **ALERTFILE** - By default, this parameter is set to *none*. This implies that by default, this test will monitor the *Soapserver.log* file available in the *c:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Services\Log* directory on Windows 2003 or the

C:\ProgramData\Citrix\Provisioning Services\Log directory on Windows 2008. If you want to monitor a different log file, specify the full path to the alert log file to be monitored. For eg., /user/john/alert_john.log. If you **ALERTFILE** specification contains 'white spaces', make sure that your specification is enclosed within "double quotes" – for example: "c:\Documents and Settings\User logs\errors.log".

Multiple log file paths can be provided as a comma-separated list - eg., "c:\Documents and Settings\All Users\logs\errors.log","c:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Server\Log\MCLI.log".

Also, instead of a specific log file, the path to the directory containing log files can be provided - eg., "c:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Server\Log". This ensures that eG monitors the most recent log files in the specified directory. Specific log file name patterns can also be specified. For example, to monitor the latest log files with names containing the strings 'soap' and 'con', the parameter specification can be: "c:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Server*soap*","c:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Server\Log*con*". Here, '*' indicates leading/trailing characters (as the case may be). In this case, the eG agent first enumerates all the log files in the specified path that match the given pattern, and then picks only the latest log file from the result set for monitoring.

You can also configure the path in the following format: *Name*@*filepath*. Here, *Name* represents the display name of the path being configured. Accordingly, the parameter specification for the 'soap' and 'con' example discussed above can be: *soaplog*@ "c:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Server\Log*soap*", *conlog*@ "c:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Server\Log*con*". In this case, the display names 'soaplog' and 'conlog' will alone be displayed as descriptors of the test.

Every time this test is executed, the eG agent verifies the following:

- Whether any changes have occurred in the size and/or timestamp of the log files that were monitoring during the last measurement period;
- Whether any new log files (that match the **ALERTFILE** specification) have been newly added since the last measurement period;

If a few lines have been added to a log file that was monitored previously, then the eG agent monitors the additions to that log file, and then proceeds to monitor newer log files (if any). If an older log file has been overwritten, then, the eG agent monitors this log file completely, and then proceeds to monitor the newer log files (if any).

5. **SEARCHPATTERN** - Enter the specific patterns of alerts to be monitored. The pattern should be in the following format: <PatternName>:<Pattern>, where <PatternName> is the pattern name that will be displayed in the monitor interface and <Pattern> is an expression of the form - *expr* or expr or *expr or expr*, etc. A leading '*' signifies any number of leading characters, while a trailing '*' signifies any number of trailing characters.

For example, say your **SEARCHPATTERN** specification is as follows: *DEBUG:DEBUG**. This indicates that "DEBUG" is the pattern name to be displayed in the monitor interface. "*DEBUG**" indicates that the test will monitor only those lines in the specified log file which start with the string "DEBUG". Similarly, if your pattern specification reads: *ERROR:ERROR*, then it means that the pattern name is *ERROR* and that the test will monitor those lines in the log which end with the term

ERROR.

A single pattern may also be of the form e1+e2, where + signifies an OR condition. That is, the <PatternName> is matched if either e1 is true or e2 is true.

Multiple search patterns can be specified as a comma-separated list. For example: `DEBUG:*DEBUG*,ERROR:*ERROR*,INFO:*INFO*,ERROR:*ERROR*,WARNING:*WARN*,FATAL:*FATAL*`

If the **ALERTFILE** specification is of the format `Name@filepath`, then the descriptor for this test in the eG monitor interface will be of the format: `Name:PatternName`. On the other hand, if the **ALERTFILE** specification consists only of a comma-separated list of log file paths, then the descriptors will be of the format: `LogFilePath:PatternName`.

If you want all the messages in a log file to be monitored, then your specification would be: `<PatternName>:*`.

6. **LINES** - Specify two numbers in the format x:y. This means that when a line in the alert file matches a particular pattern, then x lines before the matched line and y lines after the matched line will be reported in the detail diagnosis output (in addition to the matched line). The default value here is 0:0. Multiple entries can be provided as a comma-separated list.

If you give 1:1 as the value for **LINES**, then this value will be applied to all the patterns specified in the **SEARCHPATTERN** field. If you give 0:0,1:1,2:1 as the value for **LINES** and if the corresponding value in the **SEARCHPATTERN** field is like `DEBUG:*DEBUG*,ERROR:*ERROR*,INFO:*INFO*`, then:

0:0 will be applied to `DEBUG:*DEBUG*` pattern

1:1 will be applied to `ERROR:*ERROR*` pattern

2:1 will be applied to `INFO:*INFO*` pattern

7. **EXCLUDEPATTERN** - Provide a comma-separated list of patterns to be excluded from monitoring in the **EXCLUDEPATTERN** text box. For example `*critical*, *exception*`. By default, this parameter is set to 'none'.

8. **UNIQUEMATCH** - By default, the **UNIQUEMATCH** parameter is set to **FALSE**, indicating that, by default, the test checks every line in the log file for the existence of each of the configured **SEARCHPATTERNS**. By setting this parameter to **TRUE**, you can instruct the test to ignore a line and move to the next as soon as a match for one of the configured patterns is found in that line. For example, assume that `Pattern1:*FATAL*,Pattern2:*ERROR*` is the **SEARCHPATTERN** that has been configured. If **UNIQUEMATCH** is set to **FALSE**, then the test will read every line in the log file completely to check for the existence of messages embedding the strings 'FATAL' and 'ERROR'. If both the patterns are detected in the same line, then the number of matches will be incremented by 2. On the other hand, if **UNIQUEMATCH** is set to **TRUE**, then the test will read a line only until a match for one of the configured patterns is found and not both. This means that even if the strings 'FATAL' and 'ERROR' follow one another in the same line, the test will consider only the first match and not the next. The match count in this case will therefore be incremented by only 1.

9. **ROTATINGFILE** - This flag governs the display of descriptors for this test in the eG monitoring console.

If this flag is set to **true** and the **ALERTFILE** text box contains the full path to a specific (log/text) file, then, the descriptors of this test will be displayed in the following format: *Directory_containing_monitored_file:<SearchPattern>* . For instance, if the **ALERTFILE** parameter is set to "C:\ProgramData\Citrix\Provisioning Services\Log\Soapserver.log", and **ROTATINGFILE** is set to **true**, then, your descriptor will be of the following format: C:\ProgramData\Citrix\Provisioning Services\Log:<SearchPattern>. On the other hand, if the **ROTATINGFILE** flag had been set to **false**, then the descriptors will be of the following format: <FileName>:<SearchPattern> - i.e., Soapserver.log:<SearchPattern> in the case of the example above.

If this flag is set to **true** and the **ALERTFILE** parameter is set to the directory containing log files, then, the descriptors of this test will be displayed in the format: *Configured_directory_path:<SearchPattern>*. For instance, if the **ALERTFILE** parameter is set to "C:\ProgramData\Citrix\Provisioning Services\Log", and **ROTATINGFILE** is set to **true**, then, your descriptor will be: C:\ProgramData\Citrix\Provisioning Services\Log:<SearchPattern>. On the other hand, if the **ROTATINGFILE** parameter had been set to **false**, then the descriptors will be of the following format: *Configured_directory:<SearchPattern>* - i.e., Log:<SearchPattern> in the case of the example above.

If this flag is set to true and the **ALERTFILE** parameter is set to a specific file pattern, then, the descriptors of this test will be of the following format: <FilePattern>:<SearchPattern>. For instance, if the **ALERTFILE** parameter is set to "C:\ProgramData\Citrix\Provisioning Services\Log*con*", and **ROTATINGFILE** is set to **true**, then, your descriptor will be: *con*:<SearchPattern>. In this case, the descriptor format will not change even if the **ROTATINGFILE** flag status is changed.

10. **USEUTF16** - If UTF-16 encoding is to be used for reading the specified log file, then, set the **USEUTF16** flag to **true**. By default, this flag is set to **true**. If multiple log files are being monitored, then, for each file, you will have to indicate whether UTF-16 encoding is to be used for reading that file or not. For instance, assume that the **ALERTFILE** parameter is set to soaplog@ " C:\ProgramData\Citrix\Provisioning Services\Log*soap*", conlogs@ " C:\ProgramData\Citrix\Provisioning Services\Log*con*". Now, to instruct the test to use UTF-16 encoding for reading the 'soaplog' log file and not to use the UTF-16 encoding while reading the 'conlogs' log file, your **USEUTF16** setting should be as follows: *true,false*. **Note that the number of values provided against the USEUTF8 parameter should be equal to the number of log files being monitored.**
11. **DD FREQUENCY** - Refers to the frequency with which detailed diagnosis measures are to be generated for this test. The default is 1:1. This indicates that, by default, detailed measures will be generated every time this test runs, and also every time the test detects a problem. You can modify this frequency, if you so desire. Also, if you intend to disable the detailed diagnosis capability for this test, you can do so by specifying *none* against **DD FREQUENCY**.
12. **DETAILED DIAGNOSIS** - To make diagnosis more efficient and accurate, the eG Enterprise suite embeds an optional detailed diagnostic capability. With this capability, the eG agents can be configured to run detailed, more elaborate tests as and when specific problems are detected. To enable the detailed diagnosis capability of this test for a particular server, choose the **On** option. To disable the capability, click on the **Off** option.

The option to selectively enable/disable the detailed diagnosis capability will be available only if the following conditions are fulfilled:

- The eG manager license should allow the detailed diagnosis capability
- Both the normal and abnormal frequencies configured for the detailed diagnosis measures should not be 0.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
Num messages:	Indicates the number of errors that were added to the log file when the test was last executed.	Number	The value of this measure is a clear indicator of the number of “new” errors that have come into the error log of the monitored server. The detailed diagnosis of this measure, if enabled, provides the detailed descriptions of the errors of the configured patterns.

The detailed diagnosis of the *Num messages* measure, if enabled, provides the detailed descriptions of the errors of the configured patterns.

Figure 2.22: The detailed diagnosis of the Num messages measure

2.7.6 PVS Availability Check Test

This test reports whether/not the PVS server is up and running. If so, the test additionally reports the responsiveness of the server.

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : By default, the test reports one set of results for each server in the Citrix Provisional server farm being monitored

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is 54321.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface**

(**MCLI**) of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:

- Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: <System_Root>|Program Files|Citrix|Provisioning Services Console
- In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: <System_Root>|Program Files (x86)|Citrix|Provisioning Services Console

5. **DOMAIN NAME, DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:

- Should belong to the Security group with 'Farm Administrator' access.
- Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning Server host.

The steps for assigning such privileges to a user are detailed in the Section **2.1**.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN NAME**, **DOMAIN USER**, and **DOMAIN PASSWORD** of the same user.

6. Once this is done, then configure this test with the **DOMAIN NAME**, **DOMAIN USER**, and **DOMAIN PASSWORD** of a user in this security group.
7. **TARGET PORT** – This test connects to the port at which the PVS server listens and checks its availability. By default, the port number displayed against the **PORT** parameter of the test will be displayed as the **TARGET PORT**. However, If the PVS server in your environment is listening on a different port, modify the **TARGET PORT** setting to reflect the new port.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
Availability:	Indicates whether/not the PVS server is available.	Percent	The value 100 indicates that the PVS server is available. The value 0 for this measure indicates that the PVS server is not available.
Response time:	Indicates the time taken by the PVS server to respond to client requests.	Secs	Ideally, the value of this measure should be low. A high value or a steady increase in the value of this measure is a cause for concern, as it indicates poor responsiveness. This can be caused by factors such as a server bottleneck or a configuration problem.

2.8 The PVS Stores Layer

Using the tests mapped to this layer, the vDisks in each store managed by the PVS farm are discovered and the status of each vDisk can be determined. The availability and responsiveness of the default store and write cache paths can also be ascertained using these tests.

Figure 2.23: The tests mapped to the PVS Stores layer

2.8.1 PVS Stores Test

A store is the logical name for the physical location of the vDisk folder. This folder can exist on a local server or on shared storage. When vDisk files are created in the console, they are assigned to a store. Within a site, one or more Provisioning Servers are given permission to access that store in order to serve vDisks to target devices.

When a user attempts to access a desktop from a client, if the vDisk mapped to that client is inactive/locked, then such a user may be denied access to the desktop. To prevent such disasters, administrators need to promptly identify inactive vDisks and locked vDisks, and also figure out how many target devices are connecting to these vDisks, so that they can easily assess the extent of damage that this may cause. In addition, an improperly sized write-cache can also add to the monitoring troubles of administrators, as the cache may grow too big and start choking the vDisk! The size of the write-cache should hence be tracked continuously and consistent growth in size should be brought to the attention of the administrators instantly. This is where the **PVS Stores** test helps. For every vDisk in a store, this test reports whether/not that vDisk is active, locked, and mapped to target devices. If mapped, the test additionally reports the number of devices to which that vDisk is mapped. This way, the test promptly alerts administrators to the abnormal state of a vDisk and also informs administrators as to how many devices will be affected by this abnormality. Additionally, the test also periodically reports the write cache size and type of every vDisk, thus quickly intimating administrators of unexpected growth in the write-cache size, and enabling them to rapidly initiate investigations.

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : By default, the test reports one set of results for every vDisk in every store in the PVS farm being monitored

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is 54321.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface (MCLI)** of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:
 - Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: <System_Root>|Program Files|Citrix|Provisioning Services Console
 - In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: <System_Root>|Program Files (x86)|Citrix|Provisioning Services Console
5. **DOMAIN NAME**, **DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:
 - Should belong to the Security group with 'Farm Administrator' access.
 - Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning Server host.

The steps for assigning such privileges to a user are detailed in the Section 2.1.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN NAME**, **DOMAIN USER**, and **DOMAIN PASSWORD** of the same user.

6. **LOCAL HOST ONLY** - By default, this flag is set to **No**. This implies that, by default, the test auto-discovers all the servers that are part of the PVS farm, and reports metrics for each server. Setting the flag to **Yes** ensures that the test reports metrics for only that server, which is being monitored.
7. **DETAILED DIAGNOSIS** - To make diagnosis more efficient and accurate, the eG Enterprise suite embeds an optional detailed diagnostic capability. With this capability, the eG agents can be configured to run detailed, more elaborate tests as and when specific problems are detected. To enable the detailed diagnosis capability of this test for a particular server, choose the **On** option. To disable the capability, click on the **Off** option.

The option to selectively enable/disable the detailed diagnosis capability will be available only if the following conditions are fulfilled:

- The eG manager license should allow the detailed diagnosis capability;
- Both the normal and abnormal frequencies configured for the detailed diagnosis measures should not be 0.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation						
Is vDisk locked?:	Indicates whether/not this vDisk is locked.		<p>Since multiple target devices and Provisioning Servers can gain access to a single vDisk image file, it is necessary to control access to prevent corruption of the image. Should a user accidentally assign a private image to multiple target devices, and then try to boot those target devices, a corrupt image would result. Therefore, the image becomes locked appropriately for a given configuration. Target devices/Provisioning servers cannot access locked vDisks.</p> <p>If the vDisk is locked, then this measure will report the value <i>Yes</i>. If not, it will report the value <i>No</i>.</p> <p>These measure values and their corresponding numeric values are listed in the table below:</p> <table border="1" data-bbox="1008 1136 1383 1294"> <thead> <tr> <th data-bbox="1008 1136 1188 1220">Measure Value</th><th data-bbox="1188 1136 1383 1220">Numeric Value</th></tr> </thead> <tbody> <tr> <td data-bbox="1008 1220 1188 1262">Yes</td><td data-bbox="1188 1220 1383 1262">1</td></tr> <tr> <td data-bbox="1008 1262 1188 1294">No</td><td data-bbox="1188 1262 1383 1294">0</td></tr> </tbody> </table> <p>Note:</p> <p>By default, this measure reports the values <i>Yes</i> or <i>No</i> to indicate the lock status of a vDisk. The graph of this measure however, represents the lock status using the numeric equivalents - 0 or 1.</p> <p>Be aware that under certain circumstances these locks may not be released properly. A lock on a vDisk image may not be released properly when a target device machine is booted from a vDisk, and then fails (or power is</p>	Measure Value	Numeric Value	Yes	1	No	0

No	0								
vDisk size:	Indicates the size of this vDisk.	MB	Depending upon the file system used to store the vDisk, the maximum size of a vDisk is 2 terabytes (NTFS) or 4096MB (FAT).						
Target device connections:	Indicates the number of target devices that are currently connected to this vDisk.	Number	To know the names of the devices that are currently connected to a vDisk, their IP address, the site in which they operate, and the store they use, take the help of the detailed diagnosis of this measure.						
Write cache size:	Indicates the current size of the write cache of this vDisk.	MB	<p data-bbox="975 1279 1432 1691">When using Citrix Provisioning Services with the vDisk in standard mode you have a write-cache drive location that holds all the writes for the operating system. If the write-cache file is not properly sized, it may fill up unexpectedly; in this case, the operating system will behave the same as if the drive ran out of space without any warning, in other words it will blue screen.</p> <p data-bbox="975 1719 1432 1782">The optimum size of write-cache drive depends on several factors:</p> <ul data-bbox="975 1809 1432 1839" style="list-style-type: none"> <li data-bbox="975 1809 1432 1839">Frequency of server reboots. The 						

Measurement	Description	Measurement Unit	Interpretation
			<p>write-cache file is reset upon each server boot so the size only needs to be large enough to handle the volume between reboots.</p> <ul style="list-style-type: none"> Amount of free space available on the c: drive. The space that will be used for new files written to the c: drive is considered the free space available. This is a key value when determining the write-cache drive size. Amount of data being saved to the c: drive. Data that is written to the c: drive during operation will get stored automatically in the write-cache drive. New files will be stored in the write-cache file and decrease the amount of available space. Replacements for existing files will also be written to the write-cache file but will not marginally affect the amount of free space. For instance, a service pack install on a standard-mode disk will result in the write-cache file holding all the updated files, with very little change in available space. Size and location of the pagefile. When a local NTFS-formatted drive is found, Provisioning Services moves the Windows pagefile off of the c: drive to the first available NTFS drive, which is also the location of the write-cache file. Therefore, in the default configuration, the write-cache drive will end up holding both the write-cache file and the pagefile. Location of the write-cache file. The location of the write-cache file is also a factor in determining its size. The write-cache file can be held on the

Measurement	Description	Measurement Unit	Interpretation
			<p>target device's local disk, the target device's RAM, or on the streaming server.</p> <ul style="list-style-type: none"> • Target device disk: If the write-cache file is held on the target device's disk, it could be a local disk to client, local disk to the hypervisor, network storage to the hypervisor, or SAN storage to the hypervisor. • Target device RAM: If the write-cache file is held in the target device's RAM the response time will be faster and in some cases the additional RAM is less expensive than SAN disk. • Streaming Server: If the write-cache file is on the server, no preset size is necessary. When using server-side write-cache file, the Provisioning Services streaming server must have enough disk space to hold the write-cache files for all target devices managed. <p>Below are a few guidelines for right-sizing the client-side write-cache drive.</p> <ul style="list-style-type: none"> • Write-cache drive = write-cache file + pagefile (if pagefile is stored on the write-cache drive) • Write-cache file size should be equal to the amount of free space left on the vDisk image. This will work in most situations, except those where servers receive large file updates immediately after booting. As a rule, your vDisk should not be getting updated while running in standard-mode. • Always account for the pagefile location and size. If it is configured to

Measurement	Description	Measurement Unit	Interpretation
			<p>reside on the c: or d: drive, include it in all size calculations.</p> <ul style="list-style-type: none"> Set the pagefile to a predetermined size to make it easier to account for it. Letting Windows manage the pagefile size starts with 1x RAM but it could vary. Manually setting it to a known value will provide a static number to use for calculations. During the pilot, use server-side write caching to get an idea of the maximum size you might see a file reach between server reboots. Obviously, the server should have a full load and should be subject to the normal production reboot cycle for this to be of value. <p>In most situations, the recommended write-cache drive size will be free space available on vDisk image plus the pagefile size. For instance, if you have a 30GB Windows Server 2008 R2 vDisk with 16GB used (14GB free) and are running with an 8GB pagefile, it would be good practice to use a write-cache drive of 22GB calculated as 14GB free space + 8GB for the pagefile. If space doesn't permit, you have a few options, not all of which may be available to you.</p> <ul style="list-style-type: none"> If storage location for the write-cache drive supports thin-provisioning, configure thin-provisioned drives for the write-cache drive to save space; Use dynamic VHDs (instead of fixed VHDs) though this approach is generally only recommended for XenDesktop workloads. If you choose this approach, you will probably need

Measurement	Description	Measurement Unit	Interpretation																
			<p>to periodically reset the size of the dynamic VHD, which can be done with a PowerShell script.</p> <ul style="list-style-type: none"> • Reboot the servers more frequently which in turn will reduce the maximum size of the write-cache file. • Move the pagefile to a different drive or run without a pagefile. 																
Write cache type:	Indicates the write-cache type for this vDisk.		<p>The values that this measure reports and their corresponding numeric values are detailed in the table below:</p> <table border="1" data-bbox="1003 840 1379 1600"> <thead> <tr> <th data-bbox="1003 840 1150 903">Measure Value</th><th data-bbox="1150 840 1379 903">Numeric Value</th></tr> </thead> <tbody> <tr> <td data-bbox="1003 903 1150 952">Private</td><td data-bbox="1150 903 1379 952">0</td></tr> <tr> <td data-bbox="1003 952 1150 1036">Cache on Server</td><td data-bbox="1150 952 1379 1036">1</td></tr> <tr> <td data-bbox="1003 1036 1150 1121">Cache in Device RAM</td><td data-bbox="1150 1036 1379 1121">3</td></tr> <tr> <td data-bbox="1003 1121 1150 1248">Cache in Device Hard Drive</td><td data-bbox="1150 1121 1379 1248">4</td></tr> <tr> <td data-bbox="1003 1248 1150 1332">Device RAM Disk</td><td data-bbox="1150 1248 1379 1332">6</td></tr> <tr> <td data-bbox="1003 1332 1150 1438">Cache on Server Persistent</td><td data-bbox="1150 1332 1379 1438">7</td></tr> <tr> <td data-bbox="1003 1438 1150 1600">Cache in device RAM with overflow on hard disk</td><td data-bbox="1150 1438 1379 1600">9</td></tr> </tbody> </table> <p>Note:</p> <p>By default, this measure reports the Measure Values listed in the table above to indicate the write-cache type. 			numeric equivalents only.
vDisk assigned to target devices:	Indicates the number of target devices that have been assigned this vDisk.	Number	Use the detailed diagnosis of this measure to know which target devices have been assigned this vDisk.
Locked duration:	Indicates the duration for which this vDisk has been in the locked state.	Mins	<p>Since multiple target devices and Provisioning Servers can gain access to a single vDisk image file, it is necessary to control access to prevent corruption of the image. Should a user accidentally assign a private image to multiple target devices, and then try to boot those target devices, a corrupt image would result. Therefore, the image becomes locked appropriately for a given configuration.</p> <p>Target devices/Provisioning servers will not be able to access locked vDisks until the lock is released. This is why, a very low value of this measure is ideal.</p>

The detailed diagnosis of the *Is vDisk locked?* measure reveals the site name, internal name of the locked vDisk, the full path to the original vDisk file, and the name of the server where the store containing the vDisk exists.

Figure 2.24: The detailed diagnosis of the *Is vDisk locked?* measure

2.8.2 PVS Default Store Path Test

When configuring a store, administrators need to provide the default path to the store – this path represents the physical path to the vDisk. When a target device (desktop computer or server) boots, the Provisioning server checks the database for the Store name and the physical location where the vDisk assigned to that device resides, in order to provide it to the target device. If this path is unavailable or is slow, then the target

device may not even boot. This is bound to leave users accessing those devices frustrated! To ensure that the user experience with PVS is top notch, administrators should identify unavailable and least responsive default store paths much before users complain of access delays. This is where the **PVS Default Store Path** test helps. This test auto-discovers the default path configured for each store and proactively alerts administrators to the non-availability of a default store path and slowness in accessing the vDisk via the default store path. This way, the test pinpoints unavailable store paths and the ones that are slow.

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : One set of results for the default store path of each store assigned to the Provisioning server being monitored

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is 54321.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface (MCLI)** of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:
 - Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: *<System_Root>|Program Files|Citrix|Provisioning Services Console*
 - In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: *<System_Root>|Program Files (x86)|Citrix|Provisioning Services Console*
5. **DOMAIN NAME**, **DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:
 - Should belong to the Security group with 'Farm Administrator' access.
 - Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning Server host.

The steps for assigning such privileges to a user are detailed in the Section **2.1**.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN NAME**, **DOMAIN USER**, and **DOMAIN PASSWORD** of the same user.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
Store availability: path	Indicates whether/not this default store path is available.	Percent	<p>This measure reports the value 100 if the store path is available, and 0 if it is not.</p> <p>Compare the value of this measure across store paths to identify those that are currently unavailable.</p> <p>Breaks in network connection and absence of required access permissions are some of the common reasons for the non-availability of a store path.</p> <p>For high availability of store paths, you may want to configure an override store path for each store. This way, if the default store path is unavailable for any reason, Provisioning services will automatically look up the override path to deliver vDisks to users.</p>
Store path access time:	Indicates the time taken to access the vDisk via this default store path.	Secs	A low value is desired for this measure. A consistent increase in this value is a cause for concern, as it indicates that responsiveness of the default store path is deteriorating. This could be owing to a flaky network connection. It could also be due to the concurrent usage of the store path by multiple target devices.

2.8.3 PVS Default Write Cache Paths Test

The write cache includes data written by the target device. If data is written to the PVS server vDisk in a caching mode, the data is not written back to the base vDisk. Instead, it is written to a write cache file.

If the default path to this write cache file is unavailable, then the client would hang. Similarly if the write cache path is available but cannot be accessed quickly, then target devices may not be able to write changes to the cache as fast as they occur. Naturally therefore, the base vDisk will be updated with the changes only much later. Until then, target devices will be provided with an outdated vDisk upon boot.

To avoid such anomalies, administrators must be able to tell which write cache path is unavailable and which takes a long time to access, well before they impact user experience. This is where the **PVS Default Write Cache Paths** test helps. For each default write cache path it auto-discovers, this test reports the availability of the path and its access time. In the process, it pinpoints unavailable write cache paths and those that take too long to be accessed. Once the problematic paths are isolated, administrators can rapidly initiate investigations into the root-cause and swiftly resolve it.

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : One set of results for the default write cache path of each store assigned to the Provisioning server being monitored

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is 54321.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface (MCLI)** of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:
 - Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: *<System_Root>|Program Files|Citrix|Provisioning Services Console*
 - In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: *<System_Root>|Program Files (x86)|Citrix|Provisioning Services Console*
5. **DOMAIN NAME**, **DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:
 - Should belong to the Security group with 'Farm Administrator' access.
 - Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning Server host.

The steps for assigning such privileges to a user are detailed in the Section **2.1**.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN NAME**, **DOMAIN USER**, and **DOMAIN PASSWORD** of the same user.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
Write availability: path	Indicates whether/not this default write cache path is available.	Percent	<p>This measure reports the value 100 if the write cache path is available, and 0 if it is not.</p> <p>Compare the value of this measure across write cache paths to identify those that are currently unavailable.</p> <p>For high availability of write cache paths, you may want to use the 'multiple write cache paths' option that Citrix PVS offers. The multiple write cache paths (for a store) option provides the capability of distributing the write cache files across multiple physical media. When a target device starts the server chooses one of the write cache paths from the list based upon the MAC address of the client. The goal of selecting a path based on the MAC address is to get an even distribution of the clients across the available paths. The algorithm selects the same path for a given client each time that client is booted.</p> <p>This functionality is needed to ensure that during a High Availability (HA) failover the (new) server would choose the same write cache for the client (otherwise it would not be able to find the write cache file and the client would hang). If the defined write cache path is not available to a server, the server falls back to the standard vDisk path.</p>
Write path access time:	Indicates the time taken to access the write cache file in this path.	Secs	A low value is desired for this measure. A consistent increase in this value is a cause for concern, as it indicates that

Measurement	Description	Measurement Unit	Interpretation
			responsiveness of the default store path is deteriorating. This could be owing to a flaky network connection. It could also be because the path is overloaded with write requests from target devices. In case of the latter, you may want to consider using the 'multiple write cache paths' feature offered by Citrix PVS. This capability enables write cache files to be distributed across multiple physical media. This feature helps to improve I/O throughput for heavily loaded servers, and thus improves the responsiveness of write cache paths.

2.9 The PVS Devices Layer

The test mapped to this layer promptly reports the inactive target devices in a device collection.

The screenshot shows a software interface titled 'PVS Devices'. The main window displays a list of target devices under a 'PVS Target Devices' collection. The collection is expanded, showing 14 individual devices, each marked with a green checkmark. The devices are listed as follows:

- CPSWIN7-0001
- CPSWIN7-0002
- CPSWIN7-0003
- CPSWIN7-0004
- CPSWIN7-0005
- CPSWIN7-0006
- CPSWIN7-0007
- CPSWIN7-0008
- CPSWIN7-0009
- cpvs71-0001
- cpvs71-0002
- cpvs71-0003
- egpvs01

Figure 2.25: The test mapped to the PVS Devices layer

2.9.1 Device Collections Test

Device collections provide the ability to create and manage logical groups of target devices, which are typically created and managed by a “Device Administrator” (a farm and site administrator can also perform a device administrator’s tasks).

A device collection could represent a physical location, a subnet range, or a logical grouping of target devices. Creating Device Collections simplifies device management by performing actions at the collection level rather than at the target device level.

A target device can only be a member of one Device Collection.

This test monitors each device collection in the target site, and reports the active and inactive devices in each collection.

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : One set of results for every device collection configured in the target site

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is 54321.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface (MCLI)** of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:
 - Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: <System_Root>|Program Files|Citrix|Provisioning Services Console
 - In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: <System_Root>|Program Files (x86)|Citrix|Provisioning Services Console
5. **DOMAIN NAME**, **DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:
 - Should belong to the Security group with 'Farm Administrator' access.
 - Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning Server host.

The steps for assigning such privileges to a user are detailed in the Section 2.1.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN NAME**, **DOMAIN USER**, and **DOMAIN PASSWORD** of the same user.

6. **DETAILED DIAGNOSIS** - To make diagnosis more efficient and accurate, the eG Enterprise suite embeds an optional detailed diagnostic capability. With this capability, the eG agents can be configured to run detailed, more elaborate tests as and when specific problems are detected. To enable the detailed diagnosis capability of this test for a particular server, choose the **On** option. To disable the capability, click on the **Off** option.

The option to selectively enable/disable the detailed diagnosis capability will be available only if the following conditions are fulfilled:

- The eG manager license should allow the detailed diagnosis capability;
- Both the normal and abnormal frequencies configured for the detailed diagnosis measures should not be 0.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
Total devices:	Indicates the total number of target devices in this device collection.	Number	
Active devices:	Indicates the number of target devices in this device collection that are currently connected to a vDisk.	Number	Use the detailed diagnosis of this measure to know which target devices in the collection are currently active.
Inactive devices:	Indicates the target devices in this collection that are not connected to any vDisk.	Number	Use the detailed diagnosis of this measure to know which target devices in the collection are currently inactive.

Use the detailed diagnosis of the *Inactive devices* measure to know which target devices in the collection are currently inactive. For each inactive device, the detailed diagnosis will reveal the device name, the MAC address, whether the device is booting from a vDisk or not and if so which vDisk, which server is associated with the device, and whether the server IP address is down/up.

Details of all target inactive devices						
Time	Target device name	MAC	Booting from	vDisk for this device	Server ip address	Server name
Dec 16, 2010 19:36:44	basedesk21	A6-2B-1D-A8-04-6E	vDisk	S1Store1\vvDisk2	down	-

Figure 2.26: The detailed diagnosis of the Inactive devices measure

2.9.2 PVS Target Devices Test

Provisioning Services provides administrators the ability to virtualize a hard disk or workload and then stream it back out to multiple devices. The workloads, which can be server or desktop, are ripped from a physical or virtual disk into Microsoft's virtual hard disk (VHD) format and treated as a golden master image called a vDisk. This master image is then streamed over the network from a Windows server running the stream service to multiple target devices that were PXE booted. When a vDisk is in private mode, the vDisk can be edited. When a vDisk is in standard mode, it is read-only and no changes can be made to it. Instead all disk write operations are redirected to what is referred to as a write-cache file. The intelligent device drivers are smart enough to redirect writes to the write-cache file and read newly written files from the write-cache file instead of the server when necessary. When using Citrix Provisioning Services with the vDisk in standard mode you have a write-cache drive location that holds all the writes for the operating system. If the write-cache file fills up unexpectedly, the operating system will behave the same as if the drive ran out of space without any warning - in other words, it will blue screen. To avoid this, it is imperative to continuously track the usage of the write-cache, so that you can be forewarned of a probable space crunch in the write-cache and can resize the write-cache file to accommodate subsequent writes. The **PVS Target Devices** test enables this analysis.

This test helps administrators keep tabs on the usage of the write-cache of every target device that is connected to the Provisioning server, and sends out proactive alerts to administrators if it finds that a write-cache file is rapidly filling up. This way, the test aids in averting operating system crashes that may occur owing to lack of space in the write-cache. Moreover, in the process of monitoring the I/O activity on the Citrix PVS, the test also promptly captures I/O transaction failures and reports the number of times each target device had to retry an I/O transaction on the PVS. This will shed light on communication issues that may exist between the target device and the PVS.

Target of the test : Citrix Provisioning server

Agent deploying the test : An internal agent

Outputs of the test : By default, the test reports one set of results for each target device mapped to every PVS server in the farm being monitored

Configurable parameters for the test

1. **TEST PERIOD** – How often should the test be executed
2. **HOST** – The host for which the test is to be configured
3. **PORT** – Refers to the port used by the Citrix Provisioning server. By default, this is 54321.
4. **MCLI PATH** – This test executes commands using the **Management Command Line Interface (MCLI)** of the Provisioning server to collect the required metrics. To enable the test to execute the commands, the eG agent, by default, auto-discovers the full path **MCLI.exe** on the target Provisioning server. This is why, the **MCLI PATH** is set to *none* by default. If, for some reason, the eG agent is unable to auto-discover the **MCLI** path, then you will have to manually specify the path here using the following pointers:

- Typically, in a 32-bit Windows system, the **MCLI.exe** will be available in the following location by default: <System_Root>\Program Files\Citrix\Provisioning Services Console
- In a 64-bit Windows system on the other hand, the **MCLI.exe** will be available in the following location by default: <System_Root>\Program Files (x86)\Citrix\Provisioning Services Console

5. **DOMAIN NAME, DOMAIN USER** and **DOMAIN PASSWORD** – To report farm-related metrics, this test should run using the credentials of a user who fulfills the following requirements:

- Should belong to the Security group with 'Farm Administrator' access.
- Should be assigned the **Allow log on locally** security privilege on the Citrix Provisioning Server host.

The steps for assigning such privileges to a user are detailed in the Section **2.1**.

Once you assigned the aforesaid privileges to the user, then configure this test with the **DOMAIN NAME, DOMAIN USER**, and **DOMAIN PASSWORD** of the same user.

6. **LOCAL HOST ONLY** - By default, this flag is set to **No**. This implies that, by default, the test auto-discovers all the servers that are part of the PVS farm, and reports metrics for each server. Setting the flag to **Yes** ensures that the test reports metrics for only that server, which is being monitored.

7. **SHOW ACTIVE TARGETS ONLY** – By default, this flag is set to **Yes**, indicating that the test will monitor only those target devices that are up and running currently, by default. To enable the test to monitor all devices, regardless of their running state, set this flag to **No**.

8. **DETAILED DIAGNOSIS** - To make diagnosis more efficient and accurate, the eG Enterprise suite embeds an optional detailed diagnostic capability. With this capability, the eG agents can be configured to run detailed, more elaborate tests as and when specific problems are detected. To enable the detailed diagnosis capability of this test for a particular server, choose the **On** option. To disable the capability, click on the **Off** option.

The option to selectively enable/disable the detailed diagnosis capability will be available only if the following conditions are fulfilled:

- The eG manager license should allow the detailed diagnosis capability;
- Both the normal and abnormal frequencies configured for the detailed diagnosis measures should not be 0.

Measurements made by the test

Measurement	Description	Measurement Unit	Interpretation
RAM cache usage:	Indicates the percentage of space in the write-cache that is currently utilized.	Percent	A high value or a consistent increase in this value is a cause for concern, as it indicates that write-cache space is being eroded. You may have to allocate more space to the write-cache to avoid a

Measurement	Description	Measurement Unit	Interpretation
			<p>complete space drain! The optimum size of write-cache drive does depend on several factors:</p> <ul style="list-style-type: none"> • Frequency of server reboots. The write-cache file is reset upon each server boot so the size only needs to be large enough to handle the volume between reboots. • Amount of free space available on the c: drive. The space that will be used for new files written to the c: drive is considered the free space available. This is a key value when determining the write-cache drive size. • Amount of data being saved to the c: drive. Data that is written to the c: drive during operation will get stored automatically in the write- cache drive. New files will be stored in the write- cache file and decrease the amount of available space. Replacements for existing files will also be written to the write-cache file but will not marginally affect the amount of free space. For instance, a service pack install on a standard-mode disk will result in the write-cache file holding all the updated files, with very little change in available space. • Size and location of the pagefile. When a local NTFS-formatted drive is found, Provisioning Services moves the Windows pagefile off of the c: drive to the first available NTFS drive, which is also the location of the write-cache file. Therefore, in the default configuration, the write-cache drive will end up holding both the write-

Measurement	Description	Measurement Unit	Interpretation
			<p>cache file and the pagefile. To learn more about correctly sizing your pagefile, see Nick Rintalan's blog, "The Pagefile Done Right!".</p> <ul style="list-style-type: none"> • Location of the write-cache file. The location of the write-cache file is also a factor in determining its size. The write-cache file can be held in any of the following destinations: • Cache on device hard drive: Write cache can exist as a file in NTFS format, located on the target-device's hard drive. This write cache option frees up the Provisioning Server since it does not have to process write requests and does not have the finite limitation of RAM. • Cache in device RAM: Write cache can exist as a temporary file in the target device's RAM. This provides the fastest method of disk access since memory access is always faster than disk access. This measure will report metrics only if the cache resides in the device RAM. • Cache in device RAM with overflow on hard disk (only available for Windows 7 and Server 2008 R2 (NT 6.1) and later): In this case, when RAM is zero, the target device write cache is only written to the local disk. When RAM is not zero, the target device write cache is written to RAM first. When RAM is full, the least recently used block of data is written to the local differencing disk to accommodate newer data on RAM. The amount of RAM specified is the non-paged

Measurement	Description	Measurement Unit	Interpretation
			<p>kernel memory that the target device will consume.</p> <ul style="list-style-type: none"> • Cache on server: Write cache can exist as a temporary file on a Provisioning Server. In this configuration, all writes are handled by the Provisioning Server, which can increase disk IO and network traffic. • Cache on server persistent: This cache option allows for the saving of changes between reboots. Using this option, after rebooting, a target device is able to retrieve changes made from previous sessions that differ from the read only vDisk image. If a vDisk is set to Cache on server persistent, each target device that accesses the vDisk automatically has a device-specific, writable disk file created. Any changes made to the vDisk image are written to that file, which is not automatically deleted upon shutdown. This saves target device specific changes that are made to the vDisk image.
Target retries: device	Indicates the number of times this target device had to retry an I/O transaction on the Citrix PVS.	Number	Retries in PVS are a mechanism to track packet drops in the streaming traffic between a Provisioning Server and a target device. When working with PVS, I/O transactions happen between the local driver on a target device machine, the network and the PVS server itself. In the case when a client fails to get a response to an I/O request, it may try to send a request again – this is called a retry.

Measurement	Description	Measurement Unit	Interpretation
			<p>While a certain amount (0-100) can be deemed acceptable, anything that's above that count is a cause of concern. Because the traffic between the PVS server and the target device is based on the not-so-reliable (however optimized by Citrix) UDP protocol, it's very important that you don't put configurations in place that would strangle that traffic to death. So, if the value of this measure is over 100 on some or most of your targets, it is a clear indication of a problem condition that needs to be addressed immediately.</p>
Memory cache size:	Indicates the current size of MB the write cache of this target device.		<p>When using Citrix Provisioning Services with the vDisk in standard mode you have a write-cache drive location that holds all the writes for the operating system. If the write-cache file is not properly sized, it may fill up unexpectedly; in this case, the operating system will behave the same as if the drive ran out of space without any warning, in other words it will blue screen.</p> <p>The optimum size of write-cache drive depends on several factors:</p> <ul style="list-style-type: none"> • Frequency of server reboots. Measurement	Description	Measurement Unit	Interpretation
			<p>is able to retrieve changes made from previous sessions that differ from the read only vDisk image. If a vDisk is set to Cache on server persistent, each target device that accesses the vDisk automatically has a device-specific, writable disk file created. Any changes made to the vDisk image are written to that file, which is not automatically deleted upon shutdown. This saves target device specific changes that are made to the vDisk image.</p> <p>Below are a few guidelines for right-sizing the client-side write-cache drive.</p> <ul style="list-style-type: none"> • Write-cache drive = write-cache file + pagefile (if pagefile is stored on the write-cache drive) • Write-cache file size should be equal to the amount of free space left on the vDisk image. This will work in most situations, except those where servers receive large file updates immediately after booting. As a rule, your vDisk should not be getting updated while running in standard-mode. • Always account for the pagefile location and size. If it is configured to reside on the c: or d: drive, include it in all size calculations. • Set the pagefile to a predetermined size to make it easier to account for it. Letting Windows manage the pagefile size starts with 1x RAM but it could vary. Manually setting it to a known value will provide a static number to use for calculations.

Measurement	Description	Measurement Unit	Interpretation
			<ul style="list-style-type: none"> During the pilot, use server-side write caching to get an idea of the maximum size you might see a file reach between server reboots. Obviously, the server should have a full load and should be subject to the normal production reboot cycle for this to be of value. <p>In most situations, the recommended write-cache drive size will be free space available on vDisk image plus the pagefile size. For instance, if you have a 30GB Windows Server 2008 R2 vDisk with 16GB used (14GB free) and are running with an 8GB pagefile, it would be good practice to use a write-cache drive of 22GB calculated as 14GB free space + 8GB for the pagefile. If space doesn't permit, you have a few options, not all of which may be available to you.</p> <ul style="list-style-type: none"> If storage location for the write-cache drive supports thin-provisioning, configure thin-provisioned drives for the write-cache drive to save space; Use dynamic VHDs (instead of fixed VHDs) though this approach is generally only recommended for XenDesktop workloads. If you choose this approach, you will probably need to periodically reset the size of the dynamic VHD, which can be done with a PowerShell script. Reboot the servers more frequently which in turn will reduce the maximum size of the write-cache file. Move the pagefile to a different drive or run without a pagefile.

Note:This test will not report the RAM cache usage and the Write cache size, if the write cache file resides in any of the following destinations:

- Cache on device hard drive
- Cache on server
- Cache on server persistent
- Cache in device RAM with overflow on hard disk

To know how write-cache on the server, server persistent, or device hard drive is used, use the **PVS Write Cache** test mapped to the **Citrix XenApp** server. For more details about this test, refer to the **Monitoring Citrix XenApp Servers** document.

The option to store the cache in device RAM with overflow on hard disk is available only from Citrix PVS 7. As mentioned already, in the case of this setting, when the memory cache is full, PVS uses the disk for storing the additional cache data (disk access is slow – so you want as much in RAM as possible). Now, the implication of this is monitoring the percentage of cache in memory is no longer as critical as before. Even if the cache is 100% full in memory, it is not an error condition. The error condition would now be if the memory cache is full and the disk on which the additional cache is stored becomes full. Hence, it is critical to monitor the disk space on the drive where the cache is stored. This is why, the **PVS Target Devices test** will not report cache-related metrics if the cache is set to be stored in device RAM with overflow on hard disk. In such a situation, if the target devices are diskless, use the Disk Space test of the Citrix PVS server to understand how the drive in which the cache is stored is being utilized and how much free space it has. On the other hand, if the target devices are configured with hard disks, then use the Disk Space – VM test of the target device to understand cache usage.

Conclusion

This document has described in detail the monitoring paradigm used and the measurement capabilities of the eG Enterprise suite of products with respect to the **Citrix Provisioning Server**. For details of how to administer and use the eG Enterprise suite of products, refer to the user manuals.

We will be adding new measurement capabilities into the future versions of the eG Enterprise suite. If you can identify new capabilities that you would like us to incorporate in the eG Enterprise suite of products, please contact support@eginnovations.com. We look forward to your support and cooperation. Any feedback regarding this manual or any other aspects of the eG Enterprise suite can be forwarded to feedback@eginnovations.com.
